8.0 Milestone

Identify the Problems

Users have reported the following:

- Connectivity issues with email server
- File transfer speeds are slow
- Intermittent connectivity

Gathering Information:

- Scope of issue, is it single user, multiple users, all users connected to specific networking device
- Are issues persistent or come and go
- Perform simple data collection using Ping, tracert and looking at any logs relevant to issues

Prioritizing:

- Start with issues affecting the most users and has biggest impact to business functions such as no internet. Or other critical infrastructure

Questions I would ask:

- How long have you been experiencing this issue
- Is the problem always there or only happening during certain parts of the day
- Is anyone else having the same problem
- Has anything changed lately, new peripherals or software

Documentation:

I would ensure all this is attached to a specific ticket for each issue and if needed device specific tickets to ensure that anyone following the ticket can see not only issues but the findings and outcomes as well

What are some common types of network attacks, such as DDoS, phishing, man-in-the-middle, and malware?

- Malware – IS short for malicious software and all encompasses viruses, trojans, unwanted popups, etc
- Phishing – Uses social engineering to try and get privileged information from users, passwords or other personal identifiable information

- Man in the Middle – A bad actor will place themselves in the middle of communications to capture packets and either snoop on them or alter them
- DDOS – Short for distributed denial of service, a bad actor will use an extensive network of compromised devices to flood a specific resource with requests to prevent legitimate activity from gaining access

How does a Distributed Denial of Service (DDoS) attack work, and what are its effects on network availability?

- A DDoS attack works by using multiple compromised devices (often part of a botnet) to flood a target with excessive requests. The target becomes overwhelmed and cannot respond to legitimate traffic. This effects the network causing slow or unreachable services, a website or email server. Network congestion as this is the essence of DDoS.
